Abstract

Using moment equations we analyze collective flavor transformation of supernova neutrinos. We study the convergence of moment equations and find that numerical results using a few moment converge quite fast. We study effects of emission angle distribution of neutrinos on neutrino sphere. We study scaling law of the amplitude of neutrino self-interaction Hamiltonian and find that it depends on model of emission angle distribution of neutrinos. Dependence of neutrino oscillation on different models of emission angle distribution is studied.

1 Introduction

Flavor transformation of neutrinos in core-collapse supernova is one of the important remaining problems in neutrino physics. This problem has been investigated by many researchers [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23]. It is realized that neutrino density above neutrino sphere in supernova can be so large that neutrino-neutrino refraction can dominate flavor transformation of neutrinos. Research on the effect of neutrino-neutrino refraction is difficult because it is caused by neutrino self-interaction and is of non-linear nature. Complete numerical analysis use discrete set of energy bins and angle bins of neutrinos. Evolutions of million equations have to be followed. It is very complicated.

In a recent work we derived a set of moment equations describing the transport and flavor transformation of neutrinos in supernova [23]. Distribution of neutrinos over angle θ_p, the angle of neutrino direction intersecting with radial direction in supernova, is encoded in moments of density matrix. The equation of neutrino is expanded using these moments. Instead of using a large number of angle bins we just need a few moments to do numerical study. It is shown that numerical works can be simplified by about two orders of magnitude in comparison with multi-angle simulation. Moreover, this formulation of neutrino in supernova also offers us a way to study the effect of emission angle distribution of neutrinos on the transport and flavor transformation of neutrinos.

In this article we analyze the effect of emission angle distribution of neutrinos. In section 2 we make a quick review on the moment equations. In section 3 we analyze the scaling behavior of the strengths of moments in different models of neutrino emission. We check convergence property of moment equations in the analysis of the strengths of moments. In section 4 we analyze effect of different models of neutrino emission on collective neutrino oscillation. We summarize in section 5.

2 Moment equations

In Ref. [23] we introduced moments of $\rho_{\vec{p}}(t,r)$, density matrix for neutrinos at given time t and radius r:

$$\rho_k(t,r,|\vec{p}|) = \int d\Omega_{\vec{p}}\ (1-\cos\theta_p)^k\ \rho_{\vec{p}}(t,r),\ k=0,1,2\cdots, \tag{1}$$

where θ_p is the angle of neutrino direction intersecting with the radial direction, as shown in Fig 1. Similarly we introduced $\bar{\rho}_k$ for anti-neutrinos. We also introduced re-scaled moments

$$\rho'_k = z^{2(k+1)}\rho_k, \tag{2}$$

where

$$z = r/r_0, \tag{3}$$

r_0 is the radius of neutrino sphere. Similarly we introduced $\bar{\rho}'_k$ for anti-neutrinos. In Fig. 1 one can see clearly

$$\sin\theta_p = \frac{r_0}{r}\sin\theta_{p0} \tag{4}$$

It is easy to see

$$1-\cos\theta_p = \left(r_0^2/r^2\right)\Big/\left(1+\sqrt{1-\frac{r_0^2}{r^2}\sin^2\theta_{p0}}\ \right). \tag{5}$$

It scales approximately as r^{-2}. Together with the scaling behavior of the zeroth moment a geometric factor $z^{-2(k+1)}$ is found for moment ρ_k. The factor $z^{2(k+1)}$ is introduced in Eq. (2) to compensate this geometric scaling factor.

Using some approximations we arrive at the following set of moment equations

$$\frac{d\rho'_k}{dr} = -r_0^{-1}Q^1_k - i[H_A,\rho'_k],\quad k=0,1,\cdots,N \tag{6}$$

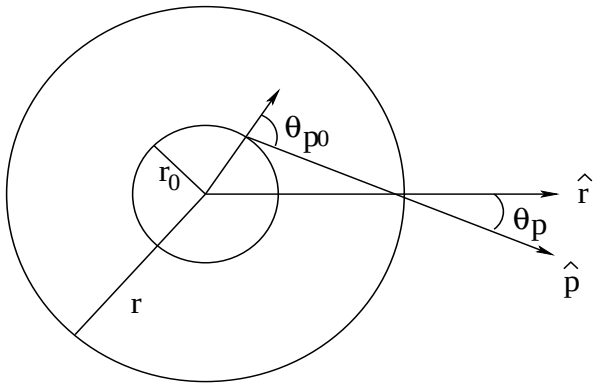

Figure 1: Geometric picture of angles of the neutrino momentum intersect with $\hat{r}$.

where $N \geq 1$ is an integer

$$Q_k^1 = z^{2k} \sum_{l=k+1}^{N} (l+1) z^{-(2l+1)} \rho_l', \tag{7}$$

$$H_A = H_0 + \sqrt{2} G_F (L + z^{-4} D_1), \tag{8}$$

$$D_1 = \int \frac{dE}{(2\pi)^3} \, E^2 \, [\rho_1'(r,E) - \bar{\rho}_1'(r,E)]. \tag{9}$$

Eq. (6) is a set of truncated moment equations in P_N approximation for which $\rho_k' = 0$ ($\bar{\rho}_k' = 0$) has been set for $k > N$. $Q_N^1 = 0$. H_0 is the Hamiltonian for vacuum oscillation, $L = diag\{n_e, n_\mu, n_\tau\}$ in the flavor base is the matter term given by charged lepton number densities $n_{e,\mu,\tau}$. G_F is the Fermi constant. Equation for $\bar{\rho}_k$ is similar except replacing H_0 by $-H_0$.

A few points concerning moment equations are as follows: a) Physical observables are described by ρ_0 and ρ_1. Integration of $E^2 Tr[\rho_0]$ over energy gives the neutrino density and integration of $E^2 Tr[\rho_0 - \rho_1]$ gives the neutrino flux; b) Emission angle distribution of neutrinos on neutrino sphere is described by moments ρ_k and their effect in the neutrino flavor transformation can be systematically studied; c) The strength of ρ_k', $Tr[\rho_k']$, is modified by Q_k^1 term and does not change if this term is neglected; d) The scaling law of the self-interaction Hamiltonian is no longer z^{-4} when $N > 1$ and is modified by higher moments. Precise scaling behavior should depend on the model of neutrino emission.

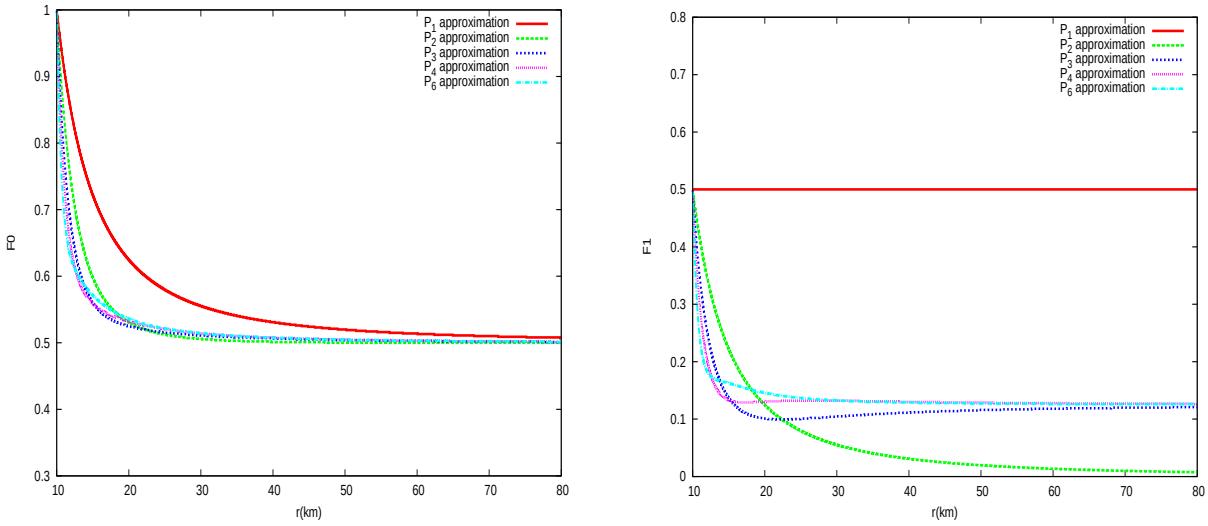

Figure 2: (color online) F_0 and F_1 in Model I.

3 Emission angle distribution and scaling law of moments

In this section we analyze the strengths of zeroth and first moments, that is $Tr[\rho_{0,1}]$, in different models of neutrino emission. This analysis can tell us a lot on how strong neutrino self-interaction is. It can also tell us a lot on the convergence property of moment equations. This is because ρ_0 and ρ_1 are the most important quantities in our problem. Physical observables are given by ρ_0 and ρ_1. When neutrino self-interaction gives dominant contribution flavor transformation of neutrinos is controlled by D_1 which is directly related to ρ_1. Effects of higher moments on $Tr[\rho_{0,1}]$ tell us how large higher moments affect the flavor transformation of neutrinos.

We consider three models of neutrino emission on neutrino sphere.

Model I, neutrino is uniformly emitted with respect to the emission angle θ_{p0} and

$$\rho_k(t, r_0) = \frac{1}{k+1}\rho_0(t, r_0) \tag{10}$$

Model II, emission angle distribution of neutrinos is proportional to $\cos\theta_{p0}$ and

$$\rho_k(t, r_0) = \frac{2}{(k+1)(k+2)}\ \rho_0(t, r_0), \tag{11}$$

Model III, emission angle distribution of neutrinos is proportional to $(1-\cos\theta_{p0})\cos\theta_{p0}$

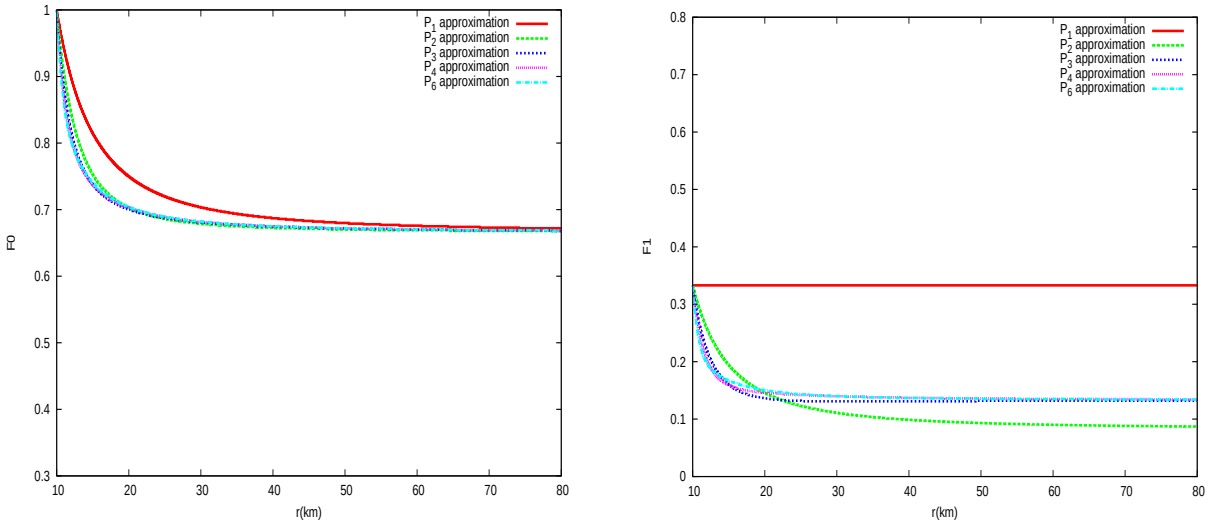

Figure 3: (color online) F_0 and F_1 in Model II.

and

$$\rho_k(t, r_0) = \frac{6}{(k+2)(k+3)}\ \rho_0(t, r_0). \tag{12}$$

The evolution of $Tr[\rho_k]$ is simple and is obtained by taking the trace of Eq. (6):

$$\frac{dTr[\rho'_k]}{dr} = -r_0^{-1} Q_k \tag{13}$$

where

$$Q_k = z^{2k} \sum_{l=k+1}^{N} (l+1) z^{-(2l+1)} Tr[\rho'_l]. \tag{14}$$

$Q_N = 0$. The second term in (6) does not contribute to $Tr[\rho'_k]$.

We do numerical analysis for F_0 and F_1:

$$F_0 = Tr[\rho'_0(r)]/Tr[\rho'_0(r_0)], \quad F_1 = Tr[\rho'_1(r)]/Tr[\rho'_0(r_0)] \tag{15}$$

$F_{0,1}$ are $Tr[\rho'_{0,1}]$ relative to $Tr[\rho'_0]$ at $r = r_0$. In our numerical analysis we work in two flavor system of (ν_e, ν_x). We choose $L_{\nu_e} = L_{\bar{\nu}_e} = L_{\nu_x} = L_{\bar{\nu}_x} = 3. \times 10^{51}$ erg/s. The initial energy spectrum of neutrino is given by the Fermi-Dirac distribution

$$f_\nu(E) = \frac{1}{N_2\ T_\nu} \frac{x^2}{e^{x-\mu_\nu} + 1}, \tag{16}$$

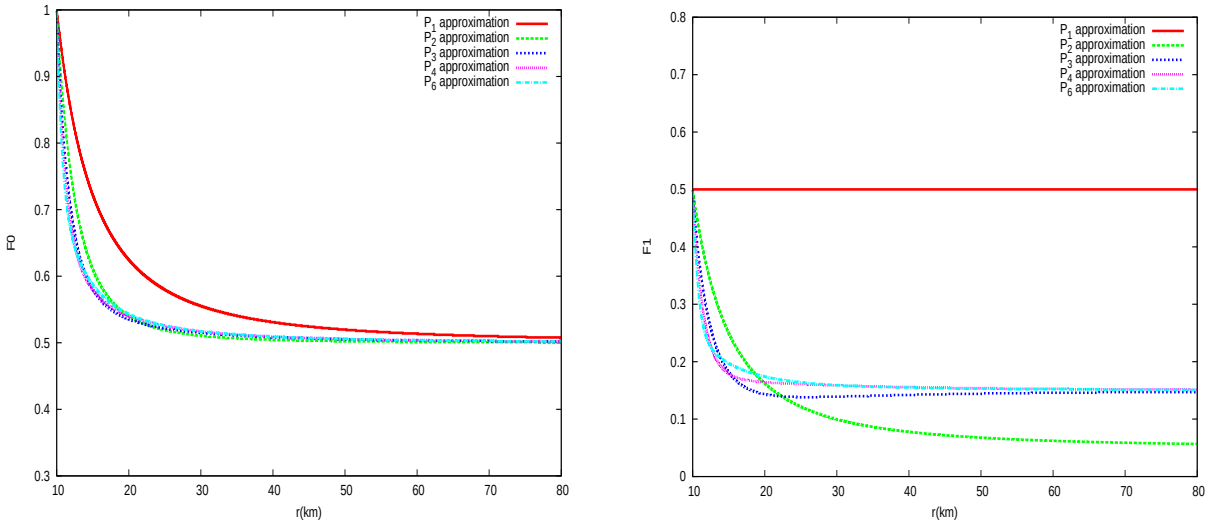

Figure 4: (color online) F_0 and F_1 in Model III.

where $x = E/T_\nu$ and N_2 is the normalization factor. Parameters of four types of neutrinos and anti-neutrinos are chosen as: $T_{\nu_e} = 2.76$ MeV, $T_{\bar{\nu}_e} = 4.01$ MeV, $T_{\nu_x} = T_{\bar{\nu}_\mu} = 6.26$ MeV. $\mu_{\nu_e} = \mu_{\bar{\nu}_e} = \mu_{\nu_x} = \mu_{\bar{\nu}_x} = 3$.

In Fig. 2, 3 and 4 we show results in Model I, II and III separetely. A number of characteristics can be read out in these figures:

i) In P_1 approximation F_1 keeps as a constant. This is because Q_1 is set to zero in this approximation.

ii) In P_2 approximation F_1 is modified. Results of F_0 do not agree with those in P_1 approximation.

iii) In P_3 approximation results of F_0 become close to those in P_2 approximations. Results of F_1 do not agree with those in P_2 approximation. This is because in P_2 approximation F_1 becomes corrected by $Tr[\rho_2']$ but $Tr[\rho_2']$ is still a constant. In P_3 approximation $Tr[\rho_2']$ is also corrected and its contribution to F_1 is modified.

iv) Results of Model II and III in P_4 and P_6 approximations agree perfectly for both F_0 and F_1.

v) Results of Model I in P_4 and P_6 approximations are in good agreement for F_0. For F_1 there are still some small differences.

A few comments are as follows:

a) Results in Model II and Model III converge faster than the results in Model I. This is in agreement with the observation that higher moments in Model II and Model III are more suppressed than those in Model I. Hence Model II and Model III should have better convergence properties.

b) Value of F_0 at large radius can be understood using flux conservation. The flux of neutrino is given by

$$Tr[\rho_0 - \rho_1] = z^{-2} Tr[\rho'_0 - z^{-2}\rho'_1] \tag{17}$$

The flux, as it should be, scales as z^{-2}(or r^{-2}) in stationary approximation. So $F_0 - z^{-2}F_1$ is a conserved quantity. At large r this quantity approaches to F_0. On the other hand its initial value can be read out directly from the models of neutrino emission. Using Eqs. (10), (11) and (12) we find that at large r

$$F_0 \to \frac{1}{2}, \quad \text{in Model I} \tag{18}$$

$$F_0 \to \frac{2}{3}, \quad \text{in Model II} \tag{19}$$

$$F_0 \to \frac{1}{2}, \quad \text{in Model III} \tag{20}$$

These values are in agreement with the plots in Figs. 2, 3 and 4.

c) The scaling behavior of F_1 tells us that in P_N approximation with $N > 1$ the self-interaction Hamiltonian scales down faster than r_0^4/r^4.

d) Numerical study shows that $Tr[\rho'_k]$ with $k > 1$ also drops down by $10^{-1} - 10^{-2}$ at large r. It is a further support to the point that moment equations converge quite fast.

4 Flavor transformation

In this section we do some analysis on flavor transformation of supernova neutrinos. We study the case of inverted mass hierarchy and for simplicity we neglect matter effect in the analysis.

In Fig. 5 we give plots of ν_e fraction versus radius. These plot are obtained by solving Eq. (6) numerically. For a small step we get

$$\rho'_k(r + \Delta r) = -\frac{\Delta r}{r_0} Q^1_k[\rho'_l(r)] + e^{-iH_A \Delta r} \rho'_k(r) e^{iH_A \Delta r} \tag{21}$$

In these plots one can see synchronized oscillation for which neutrinos of all energy point to the same direction in flavor space. Beyond the region of synchronized oscillation neutrino flavor vectors spin down which leads to neutrino flavor conversion.

We compare numerical results of P_4 approximation and of P_6 approximation in models I and III. We find nice agreements between these two approximations. This shows that P_N approximation converge quite fast. This is in agreement with the discussion in the last section that the scaling law of the strength of the Hamiltonian converge quite fast.

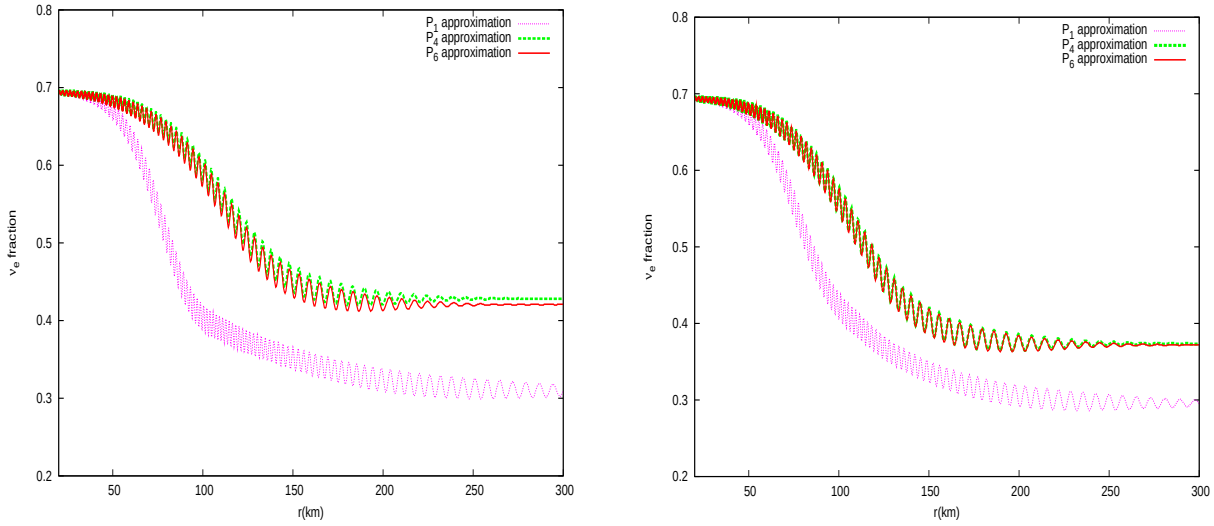

Figure 5: (color online) Fraction of ν_e, $n_{\nu_e}/(n_{\nu_e}+n_{\nu_x})$, versus radius r in in different models. Left in Model I; Right in Model II. $|\Delta m^2_{31}| = 3\times 10^{-3}\mathrm{eV}^2$, $\sin^2 2\theta_{13} = 0.01$.

In Fig. 5 one can see that result of P_1 approximation is quite different from that of P_4 and P_6 approximations. This is also consistent with discussion in the last section. Since the scaling law of the Hamiltonian in P_1 approximation is quite different from that in $P_{4,6}$ approximation we would expect to find difference in oscillation pattern.

In Fig. 6 we compare numerical results in models I, II and III. One can see that there are some differences in the oscillation pattern. This is consistent with the analysis on the strength of self-interaction Hamiltonian in these models. Numerical results show that at large r

$$F_1 \to 0.126, \quad \text{in Model I} \tag{22}$$

$$F_1 \to 0.134, \quad \text{in Model II} \tag{23}$$

$$F_1 \to 0.151, \quad \text{in Model III} \tag{24}$$

Since differences in Hamiltonian are not large at large radius and the differences in the oscillation pattern should not be large either.

We note that the scaling law of F_1, hence the amplitude of neutrino self-interaction Hamiltonian, is model dependent. This dependence on model is nicely described by the corrections given by higher moments in moment equations. Previous researches use fixed scaling function for the self-interaction Hamiltonian and do not take into account the dependence of the scaling law on the emission angle distribution of neutrinos. As a

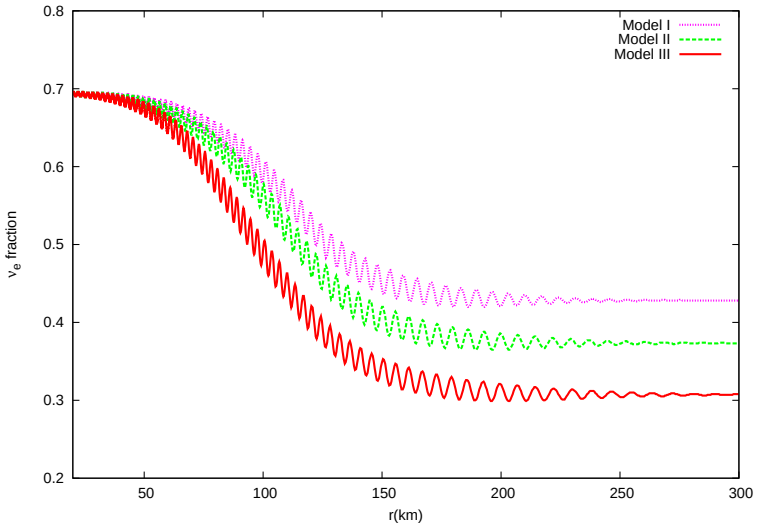

Figure 6: (color online) Fraction of ν_e, $n_{\nu_e}/(n_{\nu_e} + n_{\nu_x})$, versus radius in different models. Neutrino parameters are the same as in Fig. 5.

comparison one can check the result using a fixed scaling function. For example, one can use $\rho_1 = S^2\rho_1(r_0)$ where $S(r) = z^2/(1+\sqrt{1-z^2})$. Hence $F_1 = 0.5/(1+\sqrt{1-z^2})^2$ in model I,$F_1 = 0.33/(1+\sqrt{1-z^2})^2$ in model II and $F_1 = 0.5/(1+\sqrt{1-z^2})^2$ in model III. At large radius this model independent scaling function gives $F_1 \to 0.125$ in model I, $F_1 \to 0.083$ in model II and $F_1 \to 0.125$ in model III. Only for model I this fixed scaling function gives a correct result at large radius. In model II this fixed scaling function gives a value quite different from the value obtained using moment equations.

5 Conclusion

In summary we have analyzed some properties of moment equations and the flavor transformation of supernova neutrinos. We have analyzed the scaling behavior of neutrino density and the amplitude of self-interaction Hamiltonian of neutrinos. They are related to quantities ρ_0 and ρ_1.

We analyzed the convergence of P_N approximation of moment equations. Numerical results show that the scaling behavior of $Tr[\rho_{0,1}]$ converge for $N < 10$. We show that results of neutrino oscillation also converge quite fast. These analysis are consistent. Since the integration of $E^2\rho_1$ give the self-interaction Hamiltonian the analysis on $Tr[\rho_1]$ tell us how fast the amplitude of neutrino self-interaction converge.

We analyze neutrino flavor transformation. We find synchronized oscillation and bipolar oscillation in the oscillation pattern of supernova neutrinos. We find that oscillation

pattern of neutrinos converge quite fast for $N < 10$. The P_1 approximation can be used to make qualitative analysis but can not be used to do precise numerical study.

We study three models of emission angle distribution of neutrinos on the oscillation pattern and analyze model dependence of neutrino flavor transformation on the emission angle distribution of neutrinos. Different models of emission angle distribution can give different results in the scaling behavior of self-interaction Hamiltonian and in oscillation pattern of neutrinos. This model dependence is carefully taken into account in the correction given by higher moments in moment equations.

Previous works on oscillation of supernova neutrinos use fixed scaling function for the self-interaction Hamiltonian and do not take into the fact that the scaling law can be different in different models of neutrino emission. Analysis on the model dependent effect of emission angle distribution in neutrino oscillation is not presented in previous works.
